

Mod 5, Task 3_Question C

Position Paper (309)

Opening / Thesis: Universities should restrict faculty use of AI vendors with identifiable or confidential student data to institutionally approved tools, even when those restrictions temporarily limit pedagogical innovation.

Evidence Block 1: The NIST AI Risk Management Framework supports this position by treating AI governance as an organizational responsibility rather than a decision left entirely to individual users. Its GOVERN function states that legal and regulatory requirements involving AI should be “understood, managed, and documented,” while the MAP function requires organizations to understand the context in which an AI system will be deployed. For CTIPH, this matters because an innovative AI tool may be educationally useful while still creating unacceptable risks related to student records, survey responses, learning analytics, or other sensitive information. Faculty should not have to independently evaluate every vendor’s privacy, retention, and data-use practices.

Evidence Block 2: UNESCO provides a complementary ethical rationale, stating that privacy must be protected throughout the AI system life cycle. This is especially relevant in interprofessional education, where CTIPH works across multiple health professions programs and increasingly uses AI-supported learning experiences. Students may be required to participate in an educational activity; they should not also be required to accept unknown third-party data practices simply because an instructor finds a particular AI tool useful.

Counterargument: Restricting faculty to approved vendors can slow innovation, concentrate institutional control, and prevent educators from testing emerging tools that may offer better learning experiences than university-supported systems.

Rebuttal: That concern is legitimate, but the restriction should apply to the **data, not necessarily the experimentation**. Faculty should remain free to explore emerging AI tools with public, synthetic, or properly de-identified information. The stronger boundary is that identifiable or confidential student data should enter an AI system only after appropriate institutional review.

Closing Sentence: Universities should therefore protect faculty innovation while drawing a clear line: experimentation can remain flexible, but student data should be used only with AI vendors the institution has reviewed and approved.
